the original values free to be used by other functions and eventually be thrown away when no does not change. To create results, functions copy values and then change the copies, leaving functions do not alter parameter values, and the results that functions return are completely new side effects and uses recursion instead of loops for iteration. The functions in a functional arguments and return values. Unlike imperative and object-oriented programming, it allows no longer needed. In the simplest terms, once a value is assigned to an identifier it never changes, program are very much like mathematical functions because they do not change the state of the Pure functional programming views all programs as collections of functions that accept

beautiful, succinct solutions for many computing problems, but its stateless and recursive nature solve problems in the way you find most convenient. However, one of F#'s great strengths is that you can use multiple paradigms and mix them to makes the other paradigms convenient for handling many common programming tasks The mathematical basis for pure functional programming is elegant, and FP therefore provides

However, not many people are convinced by such arguments or in his classic paper "Why Functional Programming Matters." 90 percent assignment, and a functional program has no assignment, a functional program without considering its advantages. One could argue that since an imperative program is often When people think of functional programming, they often view its statelessness as a fatal flaw attracted to the ascetic world of stateless recursive programming, as John Hughes pointed out

what it prohibits. For example, functional programming allows you to treat functions themselves as values and pass them to other functions. This might not seem all that important at first glance, but its implications are extraordinary. Eliminating the distinction between data and To see the advantages of functional programming, you must look at what FP permits rather than

It's also common for functional languages to offer passed to a function one at a time and, if all arguments are not given, the result is a residual from mathematics and are not commonly found in imperative languages.
